

Overview of Storage and Indexing

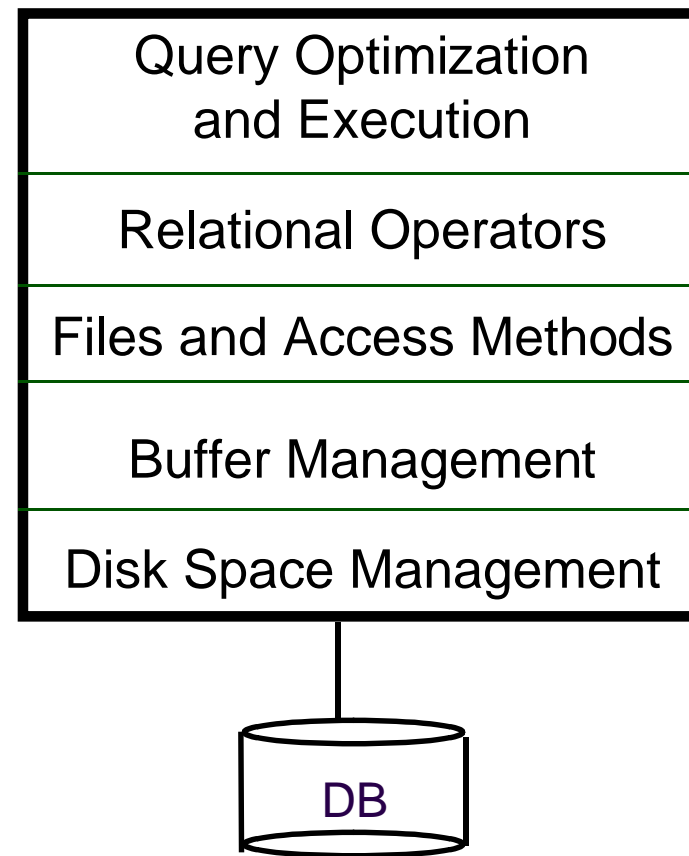

Chapter 8

Overall System Structure

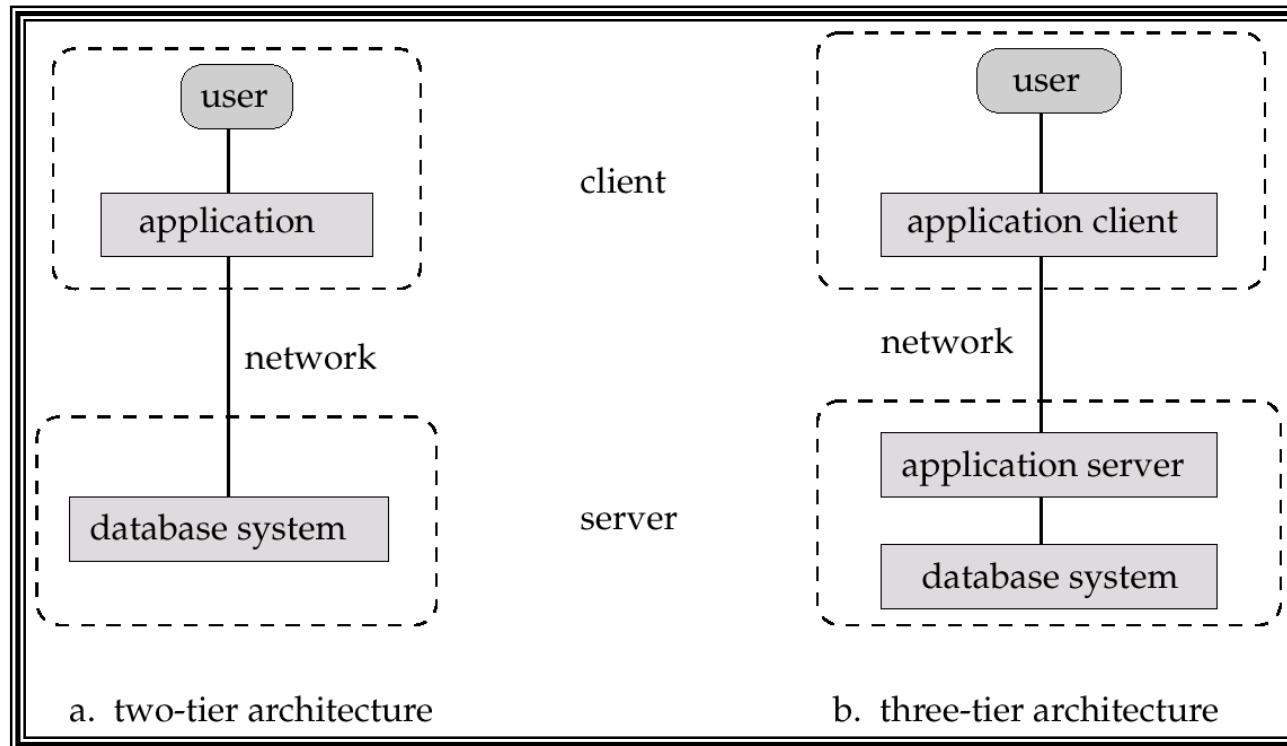

Structure of a DBMS

- ❖ A typical DBMS has a layered architecture.
- ❖ The figure does not show the concurrency control and recovery components.
- ❖ This is one of several possible architectures; each system has its own variations.

Application Architectures

- **Two-tier architecture:** E.g. client programs using ODBC/JDBC to communicate with a database
- **Three-tier architecture:** E.g. web-based applications, and applications built using “middleware”

Introduction

- ❖ In DBMS data is organized as a collection of records or a file. Each file consists of one or more pages. A page size is 4KB or 8KB.
- ❖ **“File and access methods” software layer**
 - Organizes data carefully to support fast access to desired subsets of records.
- ❖ **“File organization”**
 - Method of arranging records in a file when the file is stored on disk.
 - Example: storing employee records with <age, name and sal.> fields.
 - Question: how to store records to support multiple queries ?
 - Issue: one of the issue efficiency (other issue is correctness)

Outline

- ❖ **Data on external storage**
- ❖ File organizations and indexing
- ❖ Index data structures
- ❖ Comparison of file organizations
- ❖ Indexes and Performance Tuning

Data on External Storage

- ❖ Disks: Can retrieve random page at fixed cost
 - But reading several consecutive pages is much cheaper than reading them in random order
- ❖ Tapes: Can only read pages in sequence
 - Cheaper than disks; used for archival storage
- ❖ File organization: Method of arranging a file of records on external storage.
 - **Record id (rid)** is sufficient to physically locate record
 - **Indexes** are data structures that allow us to find the record ids of records with given values in **index search key** fields
- ❖ Architecture: **Buffer manager** stages pages from external storage to main memory buffer pool. File and index layers make calls to the buffer manager.

Outline

- ❖ Data on external storage
- ❖ **File organizations and indexing**
- ❖ Index data structures
- ❖ Comparison of file organizations
- ❖ Indexes and Performance Tuning

About Files

- ❖ DBMS abstraction: File of records
- ❖ A file can be created, destroyed
- ❖ **Records can be inserted and deleted.**
- ❖ Supports scan operations
 - Go through all records one at a time.
- ❖ Relation is stored as a file of records.
- ❖ File layer
 - Keeps track of pages allocated in a file
 - Records inserted and deleted from a file
 - Tracks available space within pages allocated to the file.

Alternative File Organizations

Many alternatives exist, *each ideal for some situations, and not so good in others:*

- Heap (random order) files: Suitable when typical access is a file scan retrieving all records.
- Sorted Files: Best if records must be retrieved in some order, or only a `range` of records is needed.
- Indexes: Data structures to organize records via trees or hashing.
 - Like sorted files, they speed up searches for a subset of records, based on values in certain (“search key”) fields
 - Updates are much faster than in sorted files.

Indexes

- ❖ An *index* on a file speeds up selections on the *search key fields* for the index.
 - Any subset of the fields of a relation can be the search key for an index on the relation.
 - *Search key* is **not** the same as *key* (minimal set of fields that uniquely identify a record in a relation).
- ❖ An index contains a collection of *data entries*, and supports efficient retrieval of all data entries \mathbf{k}^* with a given key value \mathbf{k} .

Alternatives for Data Entry k in Index

❖ Three alternatives:

- Data record with key value k
 - k is the actual record
- $\langle k, \text{rid of data record with search key value } k \rangle$
 - rid is the record id.
- $\langle k, \text{list of rids of data records with search key } k \rangle$

❖ Choice of alternative for data entries is orthogonal to the indexing technique used to locate data entries with a given key value k .

- Examples of indexing techniques: B+ trees, hash-based structures
- Typically, index contains auxiliary information that directs searches to the desired data entries

Alternatives for Data Entries (Contd.)

❖ Alternative 1:

- If this is used, index structure is a file organization for data records (instead of a Heap file or sorted file).
- At most one index on a given collection of data records can use Alternative 1. (Otherwise, data records are duplicated, leading to redundant storage and potential inconsistency.)
- If data records are very large, # of pages containing data entries is high. Implies size of auxiliary information in the index is also large, typically.

Alternatives for Data Entries (Contd.)

❖ Alternatives 2 and 3:

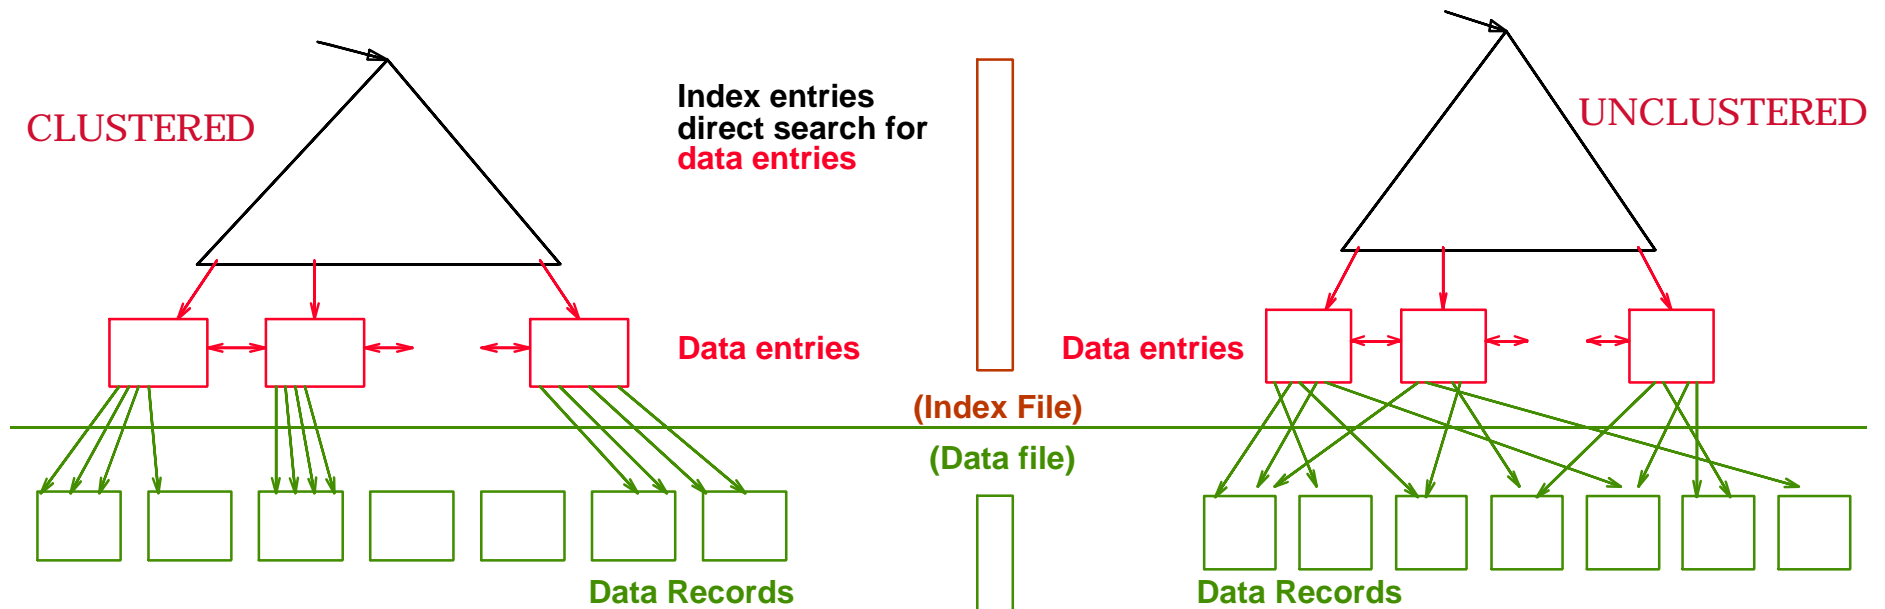

- Data entries typically much smaller than data records. So, better than Alternative 1 with large data records, especially if search keys are small. (Portion of index structure used to direct search, which depends on size of data entries, is much smaller than with Alternative 1.)
- Alternative 3 more compact than Alternative 2, but leads to variable sized data entries even if search keys are of fixed length.

Index Classification

- ❖ *Primary vs. secondary*: If search key contains primary key, then called primary index.
 - *Unique* index: Search key contains a candidate key.
- ❖ *Clustered vs. unclustered*: If order of data records is the same as, or `close to`, order of data entries, then called clustered index.
 - Alternative 1 implies clustered; in practice, clustered also implies Alternative 1 (since sorted files are rare).
 - A file can be clustered on at most one search key.
 - Cost of retrieving data records through index varies *greatly* based on whether index is clustered or not!

Clustered vs. Unclustered Index

- ❖ Suppose that Alternative (2) is used for data entries, and that the data records are stored in a Heap file.
 - To build clustered index, first sort the Heap file (with some free space on each page for future inserts).
 - Overflow pages may be needed for inserts. (Thus, order of data recs is 'close to', but not identical to, the sort order.)

Outline

- ❖ Data on external storage
- ❖ File organizations and indexing
- ❖ **Index data structures**
- ❖ Comparison of file organizations
- ❖ Indexes and Performance Tuning

Hash-Based Indexes

- ❖ Good for equality selections.
 - Index is a collection of *buckets*. Bucket = *primary page* plus zero or more *overflow pages*.
 - *Hashing function h* : $h(r)$ = bucket in which record r belongs. h looks at the *search key* fields of r .
- ❖ If Alternative (1) is used, the buckets contain the data records; otherwise, they contain $\langle \text{key}, \text{rid} \rangle$ or $\langle \text{key}, \text{rid-list} \rangle$ pairs.

B+ Tree Indexes

- ❖ Leaf pages contain **data entries**, and are chained (prev & next)
- ❖ Non-leaf pages contain **index entries** and direct searches:

Example B+ Tree

- ❖ Find 28*? 29*? All $> 15^*$ and < 30
- ❖ Insert/delete: Find data entry in leaf, then change it. Need to adjust parent sometimes.
 - And change sometimes bubbles up the tree

Outline

- ❖ Data on external storage
- ❖ File organizations and indexing
- ❖ Index data structures
- ❖ **Comparison of file organizations**
- ❖ Indexes and Performance Tuning

Cost Model for Our Analysis

We ignore CPU costs, for simplicity:

- **B:** The number of data pages
- **R:** Number of records per page
- **D:** (Average) time to read or write disk page
- Measuring number of page I/O's ignores gains of pre-fetching a sequence of pages; thus, even I/O cost is only approximated.
- Average-case analysis; based on several simplistic assumptions.

Comparing File Organizations

- ❖ Heap files (random order; insert at eof)
- ❖ Sorted files, sorted on $\langle age, sal \rangle$
- ❖ Clustered B+ tree file, Alternative (1), search key $\langle age, sal \rangle$
- ❖ Heap file with unclustered B + tree index on search key $\langle age, sal \rangle$
- ❖ Heap file with unclustered hash index on search key $\langle age, sal \rangle$

Operations to Compare

- ❖ Scan: Fetch all records from disk
- ❖ Equality search
 - Find the employee record with age 23 and sal 50.
- ❖ Range selection
 - Find all employee records with age >35
- ❖ Insert a record
- ❖ Delete a record

Assumptions in Our Analysis

❖ Heap Files:

- Equality selection on key; exactly one match.

❖ Sorted Files:

- Files compacted after deletions.

❖ Indexes:

- Alt (2), (3): data entry size = 10% size of record
- Hash: No overflow buckets.
 - 80% page occupancy \Rightarrow File size = 1.25 data size
- Tree: 67% occupancy (this is typical).
 - Implies file size = 1.5 data size

Cost of Operations

	(a) Scan	(b) Equality	(c) Range	(d) Insert	(e) Delete
(1) Heap					
(2) Sorted					
(3) Clustered					
(4) Unclustered Tree index					
(5) Unclustered Hash index					

Cost of Operations

	(a) Scan	(b) Equality	(c) Range	(d) Insert	(e) Delete
(1) Heap	BD	0.5BD	BD	2D	Search +D
(2) Sorted	BD	$D \log_2 B$	$D \log_2 B + \# \text{ matches}$	Search + BD	Search +BD
(3) Clustered	1.5BD	$D \log_F 1.5B$	$D \log_F 1.5B + \# \text{ matches}$	Search + D	Search +D
(4) Unclustered Tree index	$BD(R+0.15)$	$D(1 + \log_F 0.15B)$	$D \log_F 0.15B + \# \text{ matches}$	$D(3 + \log_F 0.15B)$	Search + 2D
(5) Unclustered Hash index	$BD(R+0.125)$	2D	BD	4D	Search + 2D

Comparison

- ❖ Heap file
 - Good storage efficiency
 - Fast scanning, insertion
- ❖ Sorted file:
 - Good storage efficiency
 - Insertion and deletion is slow
 - Searches are faster than heap
- ❖ Clustered file
 - All the advantages of sorted file and insertion and deletion is fast
 - Space overhead
- ❖ Un-clustered and hash index
 - Fast searched, insertion, and deletion
 - But, scan and range searches are slow
 - Little faster of equality searches
- ❖ Summary: ?

Comparison

- ❖ Heap file
 - Good storage efficiency
 - Fast scanning, insertion
- ❖ Sorted file:
 - Good storage efficiency
 - Insertion and deletion is slow
 - Searches are faster than heap
- ❖ Clustered file
 - All the advantages of sorted file and insertion and deletion is fast
 - Space overhead
- ❖ Un-clustered and hash index
 - Fast searched, insertion, and deletion
 - But, scan and range searches are slow
 - Little faster of equality searches
- ❖ **SUMMARY: No file organization is uniformly superior in all situation**

Outline

- ❖ Data on external storage
- ❖ File organizations and indexing
- ❖ Index data structures
- ❖ Comparison of file organizations
- ❖ **Indexes and Performance
Tuning**

Understanding the Workload

- ❖ For each query in the workload:
 - Which relations does it access?
 - Which attributes are retrieved?
 - Which attributes are involved in selection/join conditions? How selective are these conditions likely to be?
- ❖ For each update in the workload:
 - Which attributes are involved in selection/join conditions? How selective are these conditions likely to be?
 - The type of update (INSERT/DELETE/UPDATE), and the attributes that are affected.

Choice of Indexes

- ❖ What indexes should we create?
 - Which relations should have indexes? What field(s) should be the search key? Should we build several indexes?
- ❖ For each index, what kind of an index should it be?
 - Clustered? Hash/tree?

Choice of Indexes (Contd.)

- ❖ **One approach:** Consider the most important queries in turn. Consider the best plan using the current indexes, and see if a better plan is possible with an additional index. If so, create it.
 - Obviously, this implies that we must understand how a DBMS evaluates queries and creates **query evaluation plans!**
 - For now, we discuss simple 1-table queries.
- ❖ Before creating an index, must also consider the impact on updates in the workload!
 - **Trade-off:** Indexes can make queries go faster, updates slower. Require disk space, too.

Index Selection Guidelines

- ❖ Attributes in WHERE clause are candidates for index keys.
 - Exact match condition suggests hash index.
 - Range query suggests tree index.
 - Clustering is especially useful for range queries; can also help on equality queries if there are many duplicates.
- ❖ Multi-attribute search keys should be considered when a WHERE clause contains several conditions.
 - Order of attributes is important for range queries.
 - Such indexes can sometimes enable **index-only** strategies for important queries.
 - For index-only strategies, clustering is not important!
- ❖ Try to choose indexes that benefit as many queries as possible. Since only one index can be clustered per relation, choose it based on important queries that would benefit the most from clustering.

Examples of Clustered Indexes

- ❖ B+ tree index on *E.age* can be used to get qualifying tuples.

- How selective is the condition?
- Is the index clustered?

- ❖ Consider the GROUP BY query.

- If many tuples have *E.age* > 10, using *E.age* index and sorting the retrieved tuples may be costly.
- Clustered *E.dno* index may be better!

- ❖ Equality queries and duplicates:

- Clustering on *E.hobby* helps!

```
SELECT E.dno
FROM Emp E
WHERE E.age>40
```

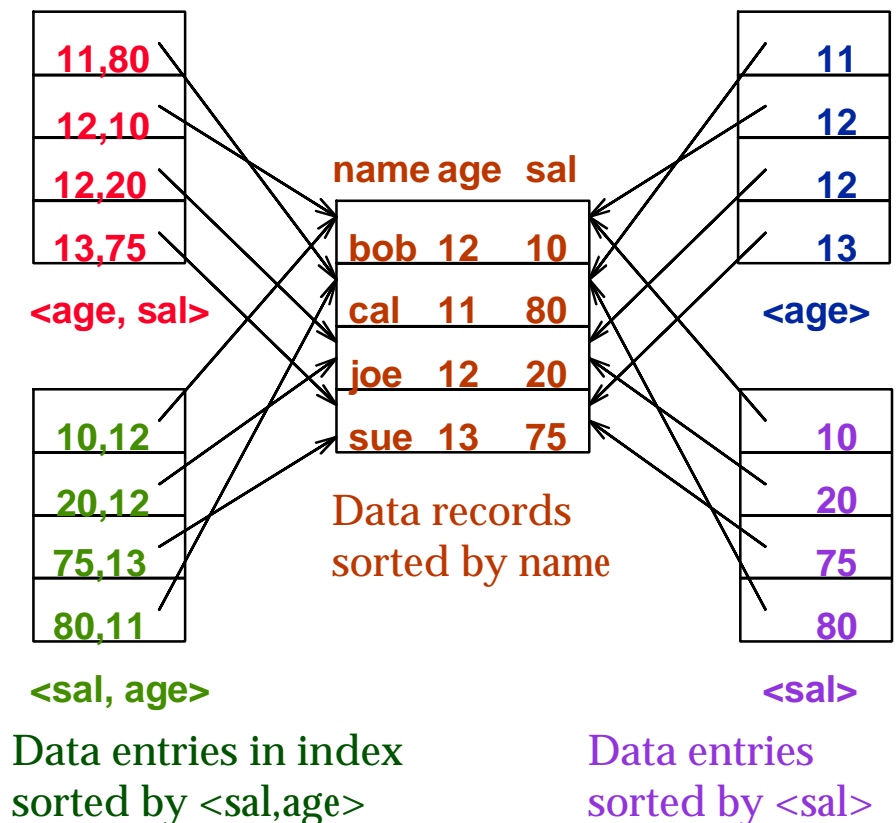

```
SELECT E.dno, COUNT (*)
FROM Emp E
WHERE E.age>10
GROUP BY E.dno
```

```
SELECT E.dno
FROM Emp E
WHERE E.hobby=Stamps
```

Indexes with Composite Search Keys

- ❖ **Composite Search Keys:** Search on a combination of fields.
 - **Equality query:** Every field value is equal to a constant value. E.g. wrt $\langle \text{sal}, \text{age} \rangle$ index:
 - age=20 and sal =75
 - **Range query:** Some field value is not a constant. E.g.:
 - age =20; or age=20 and sal > 10
- ❖ Data entries in index sorted by search key to support range queries.
 - **Lexicographic order**, or
 - **Spatial order.**

Examples of composite key indexes using lexicographic order.

Composite Search Keys

- ❖ To retrieve Emp records with $age=30$ AND $sal=4000$, an index on $\langle age, sal \rangle$ would be better than an index on age or an index on sal .
 - Choice of index key orthogonal to clustering etc.
- ❖ If condition is: $20 < age < 30$ AND $3000 < sal < 5000$:
 - Clustered tree index on $\langle age, sal \rangle$ or $\langle sal, age \rangle$ is best.
- ❖ If condition is: $age=30$ AND $3000 < sal < 5000$:
 - Clustered $\langle age, sal \rangle$ index much better than $\langle sal, age \rangle$ index!
- ❖ Composite indexes are larger, updated more often.

Index-Only Plans

```
SELECT D.mgr  
FROM Dept D, Emp E  
WHERE D.dno=E.dno
```

<E.dno>

- ❖ A number of queries can be answered without retrieving any tuples from one or more of the relations involved if a suitable index is available.

<E.dno,E.eid>
Tree index!

```
SELECT D.mgr, E.eid  
FROM Dept D, Emp E  
WHERE D.dno=E.dno
```

<E.dno>

```
SELECT E.dno, COUNT(*)  
FROM Emp E  
GROUP BY E.dno
```

<E.dno,E.sal>
Tree index!

```
SELECT E.dno, MIN(E.sal)  
FROM Emp E  
GROUP BY E.dno
```

<E. age,E.sal>
or
<E.sal, E.age>
Tree!

```
SELECT AVG(E.sal)  
FROM Emp E  
WHERE E.age=25 AND  
E.sal BETWEEN 3000 AND 5000
```

Index-Only Plans (Contd.)

❖ Index-only plans are possible if the key is <dno,age> or we have a tree index with key <age,dno>

- Which is better?
- What if we consider the second query?

```
SELECT E.dno, COUNT (*)  
FROM Emp E  
WHERE E.age=30  
GROUP BY E.dno
```

```
SELECT E.dno, COUNT (*)  
FROM Emp E  
WHERE E.age>30  
GROUP BY E.dno
```

Summary

- ❖ Many alternative file organizations exist, each appropriate in some situation.
- ❖ If selection queries are frequent, sorting the file or building an *index* is important.
 - Hash-based indexes only good for equality search.
 - Sorted files and tree-based indexes best for range search; also good for equality search. (Files rarely kept sorted in practice; B+ tree index is better.)
- ❖ Index is a collection of data entries plus a way to quickly find entries with given key values.

Summary (Contd.)

- ❖ Data entries can be actual data records, $\langle \text{key}, \text{rid} \rangle$ pairs, or $\langle \text{key}, \text{rid-list} \rangle$ pairs.
 - Choice orthogonal to *indexing technique* used to locate data entries with a given key value.
- ❖ Can have several indexes on a given file of data records, each with a different search key.
- ❖ Indexes can be classified as clustered vs. unclustered, primary vs. secondary, and dense vs. sparse. Differences have important consequences for utility/performance.

Summary (Contd.)

- ❖ Understanding the nature of the *workload* for the application, and the performance goals, is essential to developing a good design.
 - What are the important queries and updates? What attributes/relations are involved?
- ❖ Indexes must be chosen to speed up important queries (and perhaps some updates!).
 - Index maintenance overhead on updates to key fields.
 - Choose indexes that can help many queries, if possible.
 - Build indexes to support index-only strategies.
 - Clustering is an important decision; only one index on a given relation can be clustered!
 - Order of fields in composite index key can be important.
